Note to the Instructor

An effort was made to update all solutions requiring steam tables to conform with the tables in Appendix E of the book, which are based on IAPWS95). It is possible, however, that some problems may make use of older tables. Be alert as such discrepancies could confuse students even though the final answers are not much different.

Please report any mistakes or typos to Themis Matsoukas: matsoukas@psu.edu.

1 Introduction

1. Introduction

Problem 1.1 Solution

We will need the following unit conversions:

(Note on the conversion mol to lbmol: one mol has a mass equal to the molecular weight in g, while one lbmol has a mass equal equal to the molecular weight in lb.) We also need the molar mass of ammonia which is

$$M_m$$
 D 17 g/mol D 17 10 3 kg/mol

a) Specific Volume:

$$V D = \frac{1}{41:3 \text{ lb/ft}^3} D 0:02421 \text{ ft}$$
 /lb D 0:00151 m/kg D 1:51 cm/g

b) Molar Volume

$$V_{molar} \ D \ VM_m \ D \ 2:567 \quad \ 10^{-5} \ m^3/mol \ D \ 25:67 \ cm^3/mol \ D \ 0:4116 \ ft^3/lb-mol$$

Problem 1.2 Solution First we write the given equation as

$$T_K \ D \ \frac{B}{A - .ln \, P_{bar} /\!=.ln \, 10/} \quad C$$

where T_K refers to T in kelvin, P_{bar} refers to pressure in bar, and the logarithm is natural. Next we use

$$T_{e}$$
 ν 1:8. T_{K} 273:15 L 32 and P_{bar} ν $\frac{P_{psi}}{14:5}$

and substitute these values into the above equation. After some manipulation the result is

$$T_{F} \ D \ \frac{B.1:8/.\ln \ 10/}{A \ln 10 \ \ln .14:5/ \ \ln P} \ C.1:8/ \ .1:8/.273:15/ \ C.32$$

Doing the algebra,

$$T_F \ D \ \frac{5062:37}{13:2153 \ \ln P_{psi}} \quad 302:217$$

Therefore,

Problem 1.3 Solution a) The mean velocity is

$$\forall D \quad \frac{8k_B T}{m} \quad ^{1=2}$$

where $k_B \,$ D 1:38 $\,$ 10 $\,$ ²³ J=K, T D 273:16 K. The mass of the water molecule is

$$\label{eq:mdef} m\ D\ \frac{\underline{M_m}}{N_{AV}}\ D\ \frac{\underline{18}\ \underline{10}\ \underline{^{3}kg=mol}}{6:022\ \underline{10^{23}\ mol}^{1}}\ D\ 2:98904\ \ 10\ \ ^{26}\ kg:$$

The mean velocity is

This result depends only on temperature and since all three phases are the same temperature, molecules have the same mean velocity in all three phases.

b) The mean kinetic energy is

$$\cancel{E}_{kin} D \frac{1}{2} mv^2 D \frac{1}{2} m\overline{v^2}$$

where $\sqrt{2}$ is the mean squared velocity,

$$\frac{1}{v^2} \nu \frac{3k_B T}{m}$$
:

With this the mean kinetic energy is

$$\stackrel{\sim}{E}_{kin}$$
 D $\frac{3}{2}$ k_B T D 5:65441 10 ²¹ J

This is the mean kinetic energy per molecule in all phases. The number of molecules in 1 kg of water is

N D
$$\frac{1 \text{kg}}{18 \cdot 10^{-3} \text{ kg=mol}} 6=022 \cdot 10^3 \text{ D } 3:34556 \cdot 10^5$$

The total kinetic energy in 1 kg of water at 0.01 ¹C (regardless of phase) is

$$\vec{E}_{kin}$$
 D 5:65441 10 ²¹ J 3:34556 10²⁵ D 189; 171 J D 189 kJ

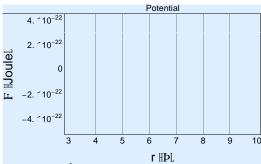

Comment: This is the translational kinetic energy of the molecule, i.e., the kinetic energy due to the motion of the center of mass. A water molecule possesses additional forms of kinetic energy that arise from the rotation of the molecule, the bending of bonds, and the vibration of oxygen and hydrogen atoms about their equilibrium positions. These are not included in this calculation as the Maxwell-Boltzmann distribution refers specifically to the translational kinetic energy.

c) The above calculation shows that the mean kinetic energy depends only on temperature (it is independent of pressure or of the mass of the molecule). Therefore, oxygen at 0.01 ¹C has the same kinetic energy as water at the same temperature:

$$\dot{E}_{kin} D \frac{3}{2} k_B T D 5:65441 10^{-21} J$$

8

Problem 1.4 Solution

a) The potential has a minimum just above 4 Å or so. To determine this value accurately we must set the

derivative of the potential equal to zero solve for the value of r. To do this easily, we define a new variable $x \ D \ r =$ and rewrite the potential as:

$$^{\circ}$$
 D a x 12 x 6

By chain rule we now have:

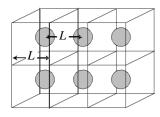

$$\frac{dF}{dr} D \frac{dF}{dx} \frac{dx}{dr} D \qquad 12x^{-13} C 6x^{-7} \frac{dx}{dr}$$

Setting this to zero and solving for x we have:

$$12x^{-13} C 6x^{-7} D 0 \rightarrow x D 2^{1=6}$$

Since r D x, the value of r that minimizes the potential is

b) If we imagine N molecules to be situated at the center of cubes whose sides are equal to r,

the volume occupied is

$$V D N.r /^3$$

These N molecules correspond to N=N_{Av} mol and their total mass is

$$M D \frac{N}{N_{AV}} M_m$$

where M_m is the molar mass of methane (M_m D 16 10 3 kg/mol). For the density, therefore, we obtain the following final formula:

$$D \frac{M_{\rm m}}{N . r /^3}$$

By numerical substitution we finally obtain the density:

$$D \; \frac{16\; 10^{-3} \text{kg/mol}}{.6:024\;\; 10^{23}\; \text{mol}} \; ^{1} \! / .4:25\; \mathring{\text{A}} \! / .10^{-10}\; \text{m/Å/} } \; D \; 346\; \text{kg/m} \qquad D \; 0:346\; \text{g/m}$$

c) Specific volumes of saturated liquid methane are listed in Perry's Handbook from which we can compute the densities. We notice (as we would have expected) that liquid volumes near the critical point (T_c D 190:55 K) vary with pressure, from 162.3 kg/m³ at the critical point to 454 kg/m³ around 90 K. Our value corresponds to Perry's tabulation at about 160 K. Our calculation is approximate and does not incorporate the effect of pressure and temperature. Notice that if we pick a distance somewhat different from r the result will change quite a bit because if the third power to which this distance is raised. But the important conclusion is that the calculation placed the density right in the correct range between the lowest and highest values listed in the tables. This says that our molecular picture of the liquid, however idealized, is fairly close to reality.

Problem 1.5 Solution

Assuming molecules to be sitting at the center of a cubic lattice with spacing L, the volume occupied by N molecules is NL^3 and the density is

$$D \, \, \frac{M_m}{N_{AV} L^3}$$

where M_{m} is the molar mass. Solving for the intermolecular distance,

$$L \, \boldsymbol{\nu} \quad \frac{M_m}{N_{AV}}$$

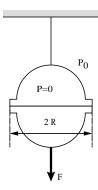

a) For liquid water with D 1000 kg=m³,

b) For steam with D 0:4 kg=m³

L D
$$\frac{18 \quad 10^{-3} \text{kg=mol}}{.6:022 \quad 10^{23} \text{ mol}^{-1}/.0:4 \text{ kg=m}^{3}/}$$
 D 4:2 10^{-9} m D 42 Å

The intermolecular distance is about 10 times larger in the vapor.

Problem 1.6 Solution

The force needed to separate the two haves is equal to the force that is exerted by pressure on one hemisphere:

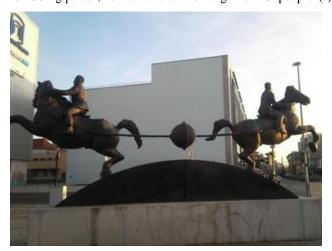

where \bullet P is the pressure difference between the atmospheric pressure and the contents of the sphere, and A is the cross-sectional area of the sphere (R^2). Assuming the sphere to be fully evacuated, the pressure difference is equal to the atmospheric pressure (1 bar D 10^5 Pa). The force now is

F D P₀.
$$R^2/D$$
 .10⁵ Pa/. 0:5² m²/D 19;635 N

This force corresponds to a mass

$$M \ D \ \frac{F}{g} \ D \ \frac{39269:9 \ N}{9:81 \ N=kg} D \ 2;000 \ kg:$$

Assuming an average weight of 80 kg/person, it would take the weight of 25 people (!) to separate the spheres.

2 Phase Diagrams of Pure Fluids

Problem 2.1 Solution a) 25 ¹C, 1 bar: liquid, because the temperature is below the saturation temperature at 1 bar (99.63 ¹C).

10 bar, 80°C: liquid, because the temperature is below the saturation temperature at 10 bar (179.88 °C).

120 ¹C, 50 bar: At 120 ¹C the vapor pressure is 198.54 kPa = 1.9884 bar. Since the actual pressure is higher, the state is liquid. (Or, at 50 bar the saturation temperature is 263.91 ¹C. Since the actual temperature is lower the state is liquid.)

- b) Liquid, because the pressure (1 atm = 760 mm Hg) is higher than the vapor pressure of bromobenzene (10 mg H) at the same temperature.
- c) Liquid, because the temperature is lower than the boiling point at the same pressure.

Note: All of these statements will make better sense if you plot your information on the P V graph.

Problem 2.2 Solution a) From steam tables at 40 bar we collect the following data:

By interpolation at V D 100 g=cm 3 D 0:1 m 3 =kg we find

Т D 600 C
$$\frac{650-600}{0:1049-0:0989}$$
.0:1 $0:0989$ / υ 609:2 1 С

The system is at 40 bar, 609.2 ¹C: the phase is vapor.

b) At 6 bar we find that the desired volume lies between that of the saturated liquid (V_L D 0:0011 m³=kg) and saturated vapor (V_V D 0:3156): the system is a vapor/liquid mixture. The vapor and liquid fractions are obtained by lever rule:

$$x_L \ D \ \frac{0.3156 \ 0.11}{0.3156 \ 0.0011} \ D \ 0.314 \ D \ 31:4\%$$

$$x_V \, D \, 1 \, 0:314 \, D \, 0:686 \, D \, 68:6\%$$

Problem 2.3 Solution a) At 1 bar, 210 ¹C, the specific volume of steam is found by interpolation to be

$$V D 2219:2 \text{ cm}^3/\text{g } D 2:2192 \text{ m}^3/\text{kg}$$

Since the total volume of the vessel is 3.5 m³, the mass is

M D
$$\frac{V^{t}}{V}$$
 D $\frac{3:5 \text{ m}^{3}}{2:2192 \text{ m}^{3}/\text{kg}}$ D 1:577 kg

b) Since the system is a mixture of liquid and vapor, it is saturated. From the saturated tables at 20 bar we find by interpolation the following:

T D 212:37
1
C; V_{L} D 1:18 cm³/g; V_{V} D 99:54 cm³/g

The specific volume of the mixture is

$$V \ D \ 1V_L \ C \ vV_V \ D \ .0:85/.1:18/ \ C \ .0:15/.99:54/ \ D \ 15:93 \ cm^3/g$$

The total volume required for storage is V ^t D M V , where V is the specific volume calculated above:

Problem 2.4 Solution Solution Initial state:

P D 45 bar; T D 257:41
1
C; V L D 1:269 cm 3 /g; V V D 44:037 cm 3 /g

The specific volume is obtained from the lever rule with $X^L D 0:25$:

$$V \ D \ x^{L} V^{L} \ C \ .1 \ x^{L} / V^{V} \ D \ .0:25 / .1:269 / \ C \ .1 \ 0:25 / .44:037 / \ D \ 33:345 \ cm^{3}/g$$

a) We know P D 80 bar, V D $33:345 \text{ cm}^3/\text{g}$. From the steam tables we find:

By interpolation at V D 33:345 cm³/g we obtain T D 388:5 ¹C. b)

From saturated tables we find:

By interpolation at V D $33:345 \text{ cm}^3/\text{g}$ we find P D 57:76 bar.

c) The volume fraction of the liquid, L , and the mass fraction of the liquid, x^{L} , are related as follows: vol. occupied by liq. $x^{L}V^{L}$

from which,

$$x^L \, D \, \frac{\sqrt{V - V} - L}{\sqrt{V - V} - \sqrt{V} - \sqrt{L} / L}$$

The saturated volumes are those at the initial state and with L D 0:25 we find

$$x^{L} \ D \ \frac{.44:037/.0:25/}{.1:269/ \ C \ .44:037 \ \ 1:269/.0:25/} \ D \ 0:920429$$

Therefore, the new specific volume in the tank is

$$V\ ^0\ D\ .0:920429/.1:269/\ C\ .1 \\ 0:920429/.44:037/\ D\ 4:6721\ cm^3/g$$

If we have mass M initially and mass M^0 at the end, we can write for the tank volume:

$$V^{t} D N V D V^{t} M^{0} \rightarrow \frac{\underline{M}}{M} D \frac{\underline{V}}{V^{0}}$$

or

$$\begin{array}{cccc} \underline{M} & \underline{M}^{\underline{0}} & \underline{V} & & \underline{33:345} \\ & & D & & 1 D & \\ \underline{M} & & V & 0 & 4:6721 & D & 6:14 \end{array}$$

Therefore, we must add 6.14 times the original mass (that's 614%).

Problem 2.5 Solution

If we interpolate for V we find

If we interpolate for we find

D 25:7681 kg=
$$m^3$$
 V D 1= D 0:0388077 m^3 =kg:

These results are quite different. Which one should we pick? For

the molar volume we have

$$V \nu \frac{ZRT}{P}$$
:

Using D 1=V, the molar density is

$$D \frac{P}{ZRT}$$
 (2.1)

We conclude that while V is inversely proportional to P , 1=V is proportional, provided that Z does not vary much in the given range. Therefore, we would accept the interpolation in .

Problem 2.6 Solution

- a) 198.3 C
- b) We first obtain the specific volumes of the saturated liquid and vapor at 15 bar:

$$V^{L} D 0:0015 \text{ m}^{3}=\text{kg}; V^{V} D 0:1317 \text{ m}^{3}=\text{kg}$$

Next we calculate the total mass of each phase:

$$m^{L}$$
 D .0:5 m^{3} /.0:0015 m^{3} =kg/ D 434:8 kg m^{V} D .11:5 m^{3} /.0:1317 m^{3} =kg/ D 87:3 kg

The total mass is

c) The quality of the steam is:

$$x^V D \frac{87:3}{522:1} D 0:167$$

d) The specific volume after 87% of the mass is removed is

$$V \,^{0} \, D \, \frac{0:13 - 522:1}{12 \, m^{3}} \, D \, 0:1768 \, m^{3} = kg$$

The temperature is obtained by interpolation at 15 bar between 250 ¹C and 300 ¹C. We find

Problem 2.7 Solution a) Since the cooker contains both vapor and liquid, the state is saturated steam. Therefore, T D T sat D 120:23 ¹C.

b) From steam tables we obtain the specific volumes of the saturated phasees:

$$V^{L} D 1:061 \text{ cm}^{3/g}; V^{V} D 885:44 \text{ cm}^{3/g}$$

The total volume of the liquid in the cooker is V $^{L;tot}$ D .0:25/.8/ liter = 2000 cm 3 . Therefore, the mass of the liquid is

$$m_L \ D \ \frac{V^{L;tot}}{V^L} \ D \ \frac{2000}{1:061} \ D \ 1885:0 \ g$$

The volume of the vapor in the cooker is $V^{L,tot}$ D .0:75/.8/ liter = 6000 cm³ and its mass is given by

$$m_V D \frac{V^{L;tot}}{V^{V}} D \frac{6000}{885:44} D 6:78 g$$

The total mass is

c) The mass fractions of the liquid (x_L) , and of the vapor (x_V) are

$$x_L \ D \ \frac{1885:0}{1885:0 \ \ 6:78} \ D \ 0:9964 \ D \ 99:64\%; \quad x_V \ D \ 1 \quad x_L \ D \ 0:004 \ D \ 0:4\%$$

Even though the vapor occupies 75% of the volume, it only represents 0.4% of the total mass.

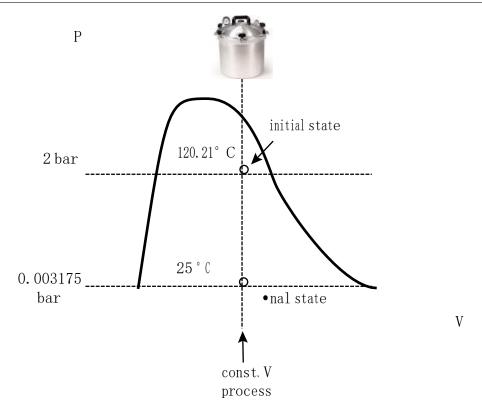

d) The quick solution is to take a look at the P V graph. The initial state is at A and the final state, B, is reached by constant-volume cooling. This state is obviously in the two-phase region because the originating state was also inside that region as well. We conclude that P D P sat .25 1 C/D 3:166 kPa. (If, however, state A were in the superheated region, we would be able to tell if B is superheated or vapor/liquid and we would have to do the solution in more detail as shown below.)

Detailed solution: The total volume of the system as well as the specific volume remain constant. The specific volume is

$$V \nu \frac{V_{cooker}}{M_{tot}} D \frac{8000 cm^3}{1891:78 g} D 4:229 cm^3 /g$$

From the saturated steam tables at 25 1 C we find, V L D 1:003 cm³/g, V V D 43400 cm³/g. The specific volume of the system is between these two values, therefore we still have a saturated system. We conclude that P D P sat .25 1 C/D 3:166 kPa D 0:03166 bar.

20

This solution is more general and will work regardless of where the initial state is.

e) When the system has cooled, the outside pressure is 1 bar and the inside pressure is 0.03166 bar. There- fore, the lid remains closed under the action of this pressure difference. The force is

$$F\ D\ R^2.P_{out}\ P_{in}/\ D\ .\ /.0:2\ m^2/.1\ 0:03166/\ bar\ 10^5 \ N/bar\ D\ 12166\ N$$

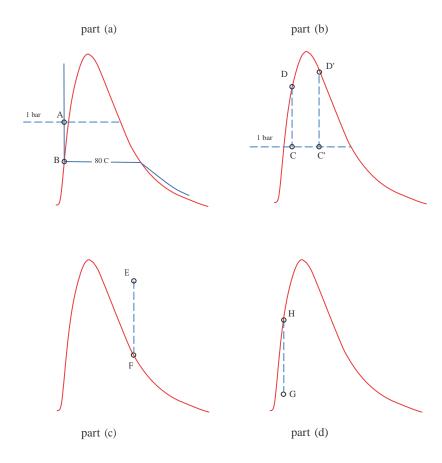

To put this force into perspective we calculate the mass whose weight is 12166 N:

$$M\ D\ \frac{F}{g}\ D\ \frac{12166\ N}{9:81\ m/s^2} D\ 1240\ kg\ D\ 2732\ lb$$

If you can lift 2700–2800 lb then you could remove that lid! (Note: Whether you take the outside pressure to be 1 bar or 1 atm or something similar, the conclusion remains that the required force is indeed very large.

Problem 2.8 Solution

It is very helpful to draw the P V graph, shown below:

a) The initial state (A) is compressed liquid (80 ¹C, 1.013 bar). The process is conducted under constant volume. Assuming the isotherm to be vertical, the final state, B, is at the same temperature and on the saturation line. Therefore: T D 80 ¹C, P D 47:36 kPa.

Notice that the temperature has not changed. This is a consequence of the fact that we have approximated the isotherm with a vertical line. In reality, the isotherm is not vertical and state B should be at a temperature somewhat below 80 ¹C. However, the steepness of the isotherm means that this temperature is very close to

- 80 °C. If we had the value of and we could calculate this temperature and would verify that it is indeed extremely close to 80 ¹C.
- b) The initial state is a V/L mixure (state C). The process is under constant volume, therefore, the final state is located at the intersection of the vertical line through C and the saturation line (state D). From steam tables: 1 bar; saturated: V_L D 1:043; V^V D 1693:7

The mass fractions of the liquid and the vapor are:

1 D
$$\frac{0:5=1:043}{0:5=1:043 \cup 0:5=1693:7}$$
 D $0:99938$

v D 1 1 D 0:00062

The specific volume at the initial state is (in cm³/g)

V D .0:99938/.1:043/ C .0:00062/.1693:7/ D 2:085

At the final state: V D 2:085, and saturated. From steam tables we find, T 367 ¹C, P D 203:13 bar (saturated liquid).

- Note 1: Even though the mass fraction of the vapor is very nearly 0, it would not be correct to set it equal to 0. While v is small, when multiplied by a large V^V it makes a significant contribution to the specific volume of the mixture. If we had set v, we would have concluded that the initial state is practically saturated liquid which means that the final pressure is almost 1 bar. Clearly, this approximation misses the right pressure by more than 200 bar!!!
- Note 2: In this case the specific volume of the vapor-liquid mixture was very close to the liquid side and for this reason the final state was liquid. In other words, under heating the vapor condenses and becomes liquid. If, however, the initial volume was much closer the vapor side (state C'), then heating would produce vapor. In this case, heating would cause the liquid to evaporate. That is, after heating the contents of the vessel the final state might either saturated vapor or saturated liquid. Can you establish a criterion for the initial specific volume to determine whether the final state is vapor or liquid?
 - c) The final state saturated vapor (state F). The process is cooling under constant volume, therefore, the initial state must be somewhere on the vertical line through F and above point F (since cooling implies that the initial state is at higher T). We conclude the initial state is superheated vapor.
 - d) By similar arguments as above, we determine that the initial state is vapor/liquid mixture. Notice that here we are heating a vapor/liquid mixture and as a result the vapor condenses to produce saturated liquid!

Problem 2.9 Solution The specific volume of water under these conditions in the tank is

V D
$$\frac{12\text{m}^3}{6:2 \text{ kg}}$$
 D 1:935 m³=kg:

According to the steam tables, the volume of saturated vapor at $1.4\,$ bar is between $1.694\,$ m 3 =kg (at $1\,$ bar) and $1.1594\,$ m 3 =kg (at $1.5\,$ bar). The calculated value is higher, therefore, the state is to the right of the saturated vapor and it must be superheated.

b) We need an entry in the steam tables such that pressure is 1.4 bar and the specific volume is 1.935 m^3 =kg. To locate this state, we interpolated in the steam tables between 1.0 bar and 1.5 bar at various temperatures and construct the table below:

T								
V .at 1:0 bar/	1:9367	2:1725	2:4062	2:6389	2:8710	3:1027	3:3342	
V .at 1:4 bar/	1:4158	1:5901	1:7623	1:9335	2:1040	2:2742	2:4442	
V .at 1:5 bar/	1:2856	1:4445	1:6013	1:7571	1:9123	2:0671	2:2217	

We can now see that the desired value is between 300 ¹C and 350 ¹C. By interpolation between these two temperatures we find

T D 300
1
C C $\frac{.350 \quad 300/{}^{1}$ C $\frac{.1:0}{bar}$.1:4 1:0/ bar ν 300:6 C

c) If we add more steam while keeping temperature constant to 300.6 C, pressure will increase and the specific volume will decrease. The vapor will become saturated when the specific volume in the tank is that of saturated vapor at 300.6 C. We obtain this value by interpolation in the saturated steam tables between 300 ¹C and 302 ¹C:

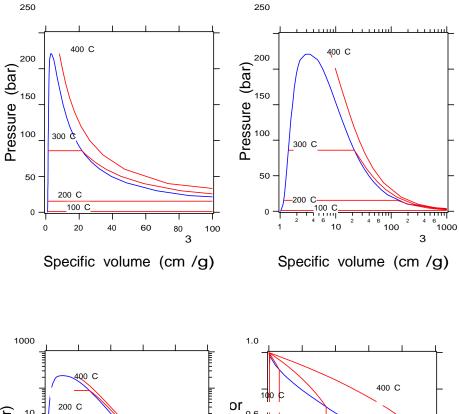

The specific volume when the tank is saturated is V D 0:0211498 m³=kg. The total mass is

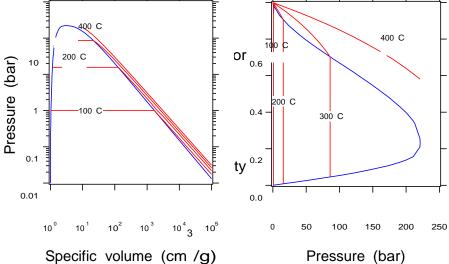

$$\frac{12 \text{ m}^3}{0:0211498 \text{ m}^3=\text{kg}} 6:2 \text{ kg D } 567:4 \text{ kg}$$

The amount that must be added is

Problem 2.10 Solution Solution

The graphs below show the P V in various combinations of linear and logarithmic coordinates and the ZP graph.

Comments:

The volumes span a very wide range and in order to see the shape of the saturation line, we must plot only a smaller range. In the above graph, the volume axis ranges from 0 to 100 cm³/mol.

By doing the V axis in log coordinates we can now look at a very wide range of values without squeezing the graph into nothingness. Notice that in the log plot the volume goes from 1 to $100,000 \text{ cm}^3/\text{g}$.

The steam tables do not contain data for the compressed liquid region and so our isotherms stop at the saturated liquid. We could extrapolate them into the liquid by drawing them as vertical lines.

The ZP graph has the familiar look. Notice that the isotherms are better separated on this graph.

Problem 2.11 Solution

a) We find that for ethane,

The reduced conditions are

$$T_r D = \frac{298:15 \text{ K}}{305:3 \text{ K}} D = 0:976; \quad P_r D = \frac{10 \text{ bar}}{48:72 \text{ bar}} D = 0:21$$

The desired isotherm is between $T_r \ D \ 0.95$ and $T_r \ D \ 1.0$. By graphical interpolation we find $Z \ 0.92$. the isotherm is fairly linear between $P_r \ D \ 0$ and the value of P_r corresponding to the given pressure, therefore, the truncated virial equation is valid.

b) The reduced conditions are

$$T_r D = \frac{244:15 \text{ K}}{305:3 \text{ K}} D 0:80; \quad P_r D = \frac{10 \text{ bar}}{48:72 \text{ bar}} D 0:21$$

Z cannot find at T_r D 0:80 under the given pressure. therefore, the truncated virial equation is not valid.

c) Since the temperature is 35¹C, lower than that boiling point, the ethane is liquid. The truncated virial equation is not valid.

26

Problem 2.12 Solution a) Vapor.

b) The molar mass can be obtained from the relationship between molar volume and density:

$$D \frac{M_m}{V} \rightarrow M_m D V$$

We know density at two pressures, so we need the molar volume in one of them. We choose the lowest pressure because at 0.01 we are justified (below) to assume ideal-gas state:

Justification: The critical pressure is not known but it must be higher than the saturation pressure at 25 C, which is 64.3 bar. That is, the reduced pressure is at most

$$\frac{0.01 \text{ bar}}{64.3 \text{ bar}}$$
 D 0.0002

From generalized graphs is it clear that at such low reduced pressures the state is essentially ideal. The molar volume is

The molar mass is

$$M_m D 0:177 \text{ kg}=\text{m}^3 .2:47882 \text{ m}^3=\text{mol}/D 43:8 10^{-3} \text{ kg}=\text{mol}$$

c) The second virial coefficient can be calculated from the truncated virial equation

$$\frac{PV}{RT}$$
 D 1 C $\frac{BP}{RT}$

We justify the use of this equation at 25 ¹C, 20 bar as follows:

Justification: The reduced temperature is $T_r \ D \ 0.97$. The reduced pressure is not known but it must be less than

$$\frac{20 \text{ bar}}{64:3 \text{ bar}} D = 0:31$$

since the critical pressure must be higher than 64.3 bar. From generalized graphs we see that for $T_r \ge 1$, the isotherm in the pressure range P_r D 0 up to about 0.31 is quite linear. This of course is a judgement call but is as good as we can do with the information we have.

Solving the truncated virial for B:

$$B\ D\ V \quad \frac{RT}{P}$$

where V D M_m = . Using the data at 20 bar with V D 0:00110239 m^3 =mol we obtain:

d) We will answer this question using the truncated virial equation

Justification: If the truncated virial is valid at 25 ¹C, 20 bar, as assumed above, it is valid for all pressures less than 20 bar.

Solving the truncated virial for V and using P D 12 bar:

$$V D \frac{RT}{P} B D 0:00192866 m^3 = mol$$

The number of moles to be stored is

$$\ \ \, n\,\,D\,\,\frac{20\,kg}{43:9-10^{-3}\,\,kg=mol}\,D\,\,456\,mol$$

and the volume of the tank is

$$V^{tank}\,D\ .456\ mol/.0:00192866\ m^3 = mol/\ D\ 0:88\ m^3$$

28

Problem 2.13 Solution a) We collect the data for this problem:

We calculate the second virial using the Pitzer equation:

$$\begin{array}{lll} T_r \ D & 1:5646 \\ P_r \ D & 0:434877 \\ B_0 \ D & 0:12319 \\ B_1 \ D & 0:112756 \\ B \ D & 0:0000420106 \ m^3 = mol \end{array}$$

The compressibility factor is

$$Z D \frac{BP_c}{RT} D 0:966104:$$

b) The molar volume in the tank is

$$V D \frac{ZR T}{P} D 0:0011974 m^3 = mol$$

The total number of moles is

n D
$$\frac{V^{tank}}{V}$$
 D 835:144 mol

c) If we double the number of moles, the new molar volume in the tank is

$$V_2 D \frac{V^{tank}}{2n} D \frac{V}{2} D 0:000598699 m^3 = mol:$$

We use the truncate virial to solve for the new pressure P_2 (since temperature is the same as before, the second virial does not need to be recalculated):

$$\frac{P V}{RT}$$
 D 1 C $\frac{BP}{RT}$ > P D $\frac{RT}{V}$ D 38:7 bar

d) To validate the applicability of the truncated virial we check with the Z^0 graph and notice that isotherms around T_r D 1:6 remain linear up to fairly high pressures. The pressure of this problem, P D 38:7 bar corresponds to P_r

D 0:84, which is still within the linear range of the isotherm, as far as we can tell by naked eye.

Summary of results

P D 20 bar T D 298:15vK V_{tank} $1:0 \text{ m}^3$ 190:56 K $T_c D$ P_c D 45:99 bar ! D 0:011 $T_r D$ 1:5646 P_r D 0:434877 B_0 D 0:12319 B₁ D 0:112756 $0:0000420106 \text{ m}^3 = \text{mol}$ ВD Z D 0:966104 $0:0011974 \text{ m}^3=\text{mol}$ V D n D 835:144 mol 1670:29 mol n_2 D $V_2 D = 0.000598699 \text{ m}^3 = \text{mol}$ P₂ D 38:6886 bar

Problem 2.14 Solution a) The critical constants and acentric factor of nitrogen are:

The reduced conditions are

$$\begin{array}{c} \text{7 bar} & \text{110 K} \\ P_{r} \text{ D} \ \overline{34:0 \text{ bar}} \text{ D 0:206;} & T_{r} \text{ D } \overline{126:2 \text{ K}} \text{ D 0:872} \end{array}$$

From Eqs (2.28), (2.29) we have

$$B^0$$
 ν 0:083 $\frac{0:422}{0:872^{1:6}} \nu$ 0:442395 B^1 ν 0:139 $\frac{0:172}{0:872^{4:2}} \nu$ 0:166745 B^0 C $!B^1$ D 0:442395 0:166745 0:038 D 0:448731

The second virial coefficient is calculated form Eq. (2.27)

The compressibility factor is

The molar volume is finally calculated to be

The mass of nitrogen in the tank

b) In this process the specific volume stays constant. For the two unkowns, P and T, we have the following two equations:

$$\frac{P \stackrel{\text{Sat}}{V}}{RT} \quad D \quad 1 C \frac{BP \stackrel{\text{Sat}}{RT}}{RT}$$

$$P \stackrel{\text{Sat}}{D} \quad e^{14:9542} \stackrel{588:72}{\underline{6:6CT}}$$

These should be solved by trial and error. For example, specify T, solve for P sat from the second equation, solve for V from first equation, and if the answer does not match the known volume, try again. The solution is as following:

T (F	()	В	P sat (mmHg)	Z	V (m ³ /mol)
100	-1.6710	10 4	5715.79	0.846850	9.2393 10 4
90	-2.0477	10 4	2684.39	0.902059	$1.8860 \ 10^{-3}$
99	-1.7038	10^{-4}	5338.88	0.052055	9.8597 10 4
98	-1.7377	10^{-4}	4979.38	0.858414	$1.0535 \ 10^{-3}$
This text 17 This	-1.7726	s, Fundamentals of Chemic	tal Engine Mino-The modynamics 0-1: 4636.94	0.864119	6-6). Copyright © 2013 Pearson

			1.1273	10^{-3}
96 -1.8085 10 ⁴	4311.17	0.869766	1.2078	10^{-3}
96.48 -1.7911 10 4	4465.49	0.867063	1.1682	10^{-3}

31

The volume solved in part a) is $1.168 10^{-3} m^3/mol$. Therefore the tempeture is 96.48 K, and the pressure is $P D 4465:49 mmHg D 5:95 10^5 Pa$.

c) The reduced state in part (a) is T_r D 0:87 and P_r D 0:206. The desired isotherm is between T_r D 0:80 and T_r D 0:90. From a generalized Z P graph we see that isotherms in this range are fairly linear, therefore the truncated virial is acceptable.

In part (b) we found T_r D 0:76 and P_r D 0:175. The desired isotherm is between T_r D 0:70 and T_r D 0:80. Again, the isotherm is fairly linear between P_r D 0 and the value of P_r corresponding to the given pressure, therefore, the truncated virial equation is valid.

Problem 2.15 Solution a) The second virial coefficient is directly related to the slope of an isotherm on the ZP graph. Specifically,

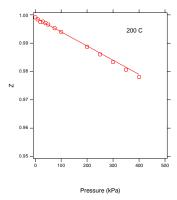

$$Z D 1 C \frac{BP}{RT} C$$
 \rightarrow $\frac{BP}{RT} D \frac{@Z}{@P} \overset{\circ}{\underset{T PD0}{\overset{\circ}{\smile}}}$

This suggests the following graphical solution: calculate Z from the steam tables at constant T, plot them versus pressure, and obtain the slope of the line near P D O. To facilitate calculations, suppose that P is in kPa, V

From the steam tables at 200 ¹C we have:

P (kPa)	$V (cm^3/g)$	\mathbf{Z}
1	218350	0.9991
10	21820	0.9984
20	10900	0.9975
30	7267.5	0.9976
40	5447.8	0.9971
50	4356.	0.9966
75	2900.2	0.9953
100	2172.3	0.9940
200	1080.4	0.9887
250	861.98	0.9861
300	716.35	0.9834
350	612.31	0.9806
400	534.36	0.9780

Notice that we had to go up to 400 kPa (4 bar) to see enough change in Z so that we can obtain the slope of the line. The graph is shown below:

The line shown is tangent to the points at P D 0 and its slope is 5:00554 10^{-5} . The easy way to draw this line is to fit a straight line through the points closest to the origin, say below 200 kPa. A smarter way is to use all the points and a quadratic equation:

Then, the equation of the tangent line at P D 0 is (why?)

and its slope is b. Following this procedure we find

The second virial coefficient is

B D .slope/.RT/D . 5:00554
$$^{10^{-8}}$$
 Pa 1 /.8:314 J/mol K/.473:15 K/D $^{1:969}$ $^{10^{-4}}$ m 3 /mol

b) Using the above value of B we can calculate the molar volume of water at 14 bar as follows:

The value from the steam tables is $142.94 \text{ cm}^3/\text{g}$. This agreement is very good indicating that the truncated virial equation is valid at these conditions.

Problem 2.16 Solution We need the density of methane under these conditions. We will calculate it via the compressibility factor using the Lee-Kesler tables. The critical parameters of methane are:

The reduced state of methane is

$$T_r D = \frac{298:15 \text{ K}}{190:6 \text{ K}} D 1:564; \qquad P_r D = \frac{75 \text{ bar}}{45:99 \text{ bar}} D 1:631$$

We must perform a double interpolation in the tables since neither value is listed. The calculation is sum-marized below:

Interpolations for \mathbb{Z}^1

Interpolations for \mathbb{Z}^0

		P_r		I	P_{r}	
	1.5	1.631	2.0	1.5	1.631	2.0
1.5	0.8689	0.8595	0.8328	0.1345	0.1466	0.1806
1.564		0.8811			0.1433	
1.6	0.9	0.8931	0.8738	0.1303	0.1414	0.1729

Here, numbers in regular font are form the Lee-Kesler tables and those in bold are interpolations. First we interpolate at T_r D 1:5 to calculate Z^0 at P_r D 1:631 and we obtain 0.8595. Next, we do the same at T_r D 0:6 to calculate Z^0 at P_r D 1:631 from which we find 0.8931. Finally, we interpolate between these two values to obtain Z^0 at T_r D 1:564 to find the value of Z^0 at the desired state. We find

$$Z^0 D 0:8811$$

The procedure is similar for \mathbb{Z}^1 where we find

With these values we calculate the compressibility factor, the molar volume, density, and total volume of the tank:

Problem 2.17 Solution a) At the given conditions, T_r D 0:963675, P_r D 0:949281. The state is very close to the critical, therefore, far removed from the ideal-gas state.

b) Using the Lee Kesler method we find

The number of moles in the tank is

$$n\ D\ \frac{200\ kg}{4410^{-3}\ kg=mol} D\ 4545:45\ mol$$

and the volume of the tank is

c) At 25 ¹C, 1 bar, CO₂ is essentially in the ideal-gas state and its molar volume is

$$V_2 D \frac{RT}{P_2} D 0:0243725 m^3$$

which means that the moles in th tank are

We must remove 199:294s kg.

Problem 2.18 Solution

\sim	. 1	•	
()	ntl	111	ie:
v	นเ	ш	ıc.

- a) Calculate P_r and T_r and find the compressibility factor using the Lee-Kesler tables or graphs.
- b) With the compressibility factor known, calculate the specific volume and then the total volume of the tank (since the total mass is known).
- c) Calculate the new molar volume after 90% (45 kg) is removed. Calculate Z. Since we know Z and T we should be able to obtain P. If we use the Lee-Kesler graph for Z we must do a trial-and-error procedure: choose P, calculate Z, if it doesn't match the known Z try another pressure and continue.

Alternatively, use the truncated virial equation: estimate B using the Pitzer correlation and use

$$\frac{PV}{RT}$$
 D 1 C $\frac{BP}{RT}$

to solve for P. Once you have obtained B, confirm that the use of the virial equation was justified.

Calculations

a) The critical parameters of ethylene are:

The reduced temperature and pressure are

$$T_{r} D = \frac{293:15 \text{ K}}{282:3 \text{ K}} D 1:05615; P_{r} D = \frac{80 \text{ bar}}{50:40 \text{ bar}} D 1:5873$$

Checking with the generalized Z graph we see that the state is well-removed from the ideal-gas state.

b) We calculate the compressibility factor using the generalized Lee-Kesler graphs (or by interpolation in tables):

As expected, the compressibility factor is quite below its ideal value. The molar volume of the gas is

$$V D Z \frac{RT}{P} D 0:00010113 m^3 = mol$$

The number of moles in the tank is

n D
$$\frac{50 \text{ kg}}{28 - 10^{-3} \text{ kg=mol}}$$
D 1785:71 mol

and the total volume is

$$V^{tot} D n V D .1785:71 mol/.0:00010113 m^3 = mol/ D 0:181 m^3$$

c) The number of moles left in the tank is

and the new molar volume is

$$V \cap D = \frac{V^{tot}}{n^0} D = 0.00101128 \text{ m}^3 = \text{mol}$$

We will use the truncated virial since it does not require iterations, but we will have to justify its use after-ward. $\stackrel{\bullet}{BP}$

$$\frac{1}{RT}$$
 D 1 C $\frac{BI}{RT}$ > P^0 D $\frac{RT}{V^0}$ B

We calculate the second virial coefficient using the Pitzer correlation:

$$B^0$$
 D 0:083 $\frac{0:422}{D}$ 0:303682
$$B^1$$
 D 0:139 $\frac{0:172}{T_r^{4:2}}$ D 0:00226241
$$B \stackrel{}{\smile} \frac{RT_c}{P_c} . B^0$$
 C $!$ B $!$ D 0:0001413 m^3 =mol

Finally, the pressure is

$$P^{0} D \frac{RT}{V^{0} B} D \underline{21:5bar}$$

Check validity of truncated virial At the final state, $T_r D 1:05615$, $P_r D 0:426709$. If the isotherm at this T_r is sufficiently linear up to $P_r D 0:426709$, the truncated virial is acceptable. The graph in the book looks "linear enough." But we want to be more precise, so we will calculate the compressibility factor form the virial equation and from the Lee-Kesler graphs and will compare:

Using the virial equation:

$$Z D 1 C \frac{BP^{0}}{RT} D 0:877$$

Using the Lee-Kesler tables we find Z⁰ D 0:8677, Z¹ D 0:007497 and

Pretty close.

Note: We could have used the ideal-gas law subject to the same condition: after the calculation we should check whether the ideal-gas assumption is correct or not:

$$P^{0} D \frac{RT}{V} D 24:5 bar$$

With T_r D 1:05615, P_r D 24:5=50:40 bar D 0:486, the Lee-Kesler charts give Z D 0:846. This value is more than 5% way from the ideal-gas state, therefore, we reject the calculation.

Trial and error Here is how to perform a trial-and error solution using the Lee-Kesler tables. We need a starting guess for P - we will use the result fo the ideal-gas calculation, P_{guess} D 24:5 bar. From the Lee-Kesler tables we find

$$Z^0 \ D \ 0:846798; \quad Z^1 \ D \quad 0:00762552; \quad Z_{guess} \ D \ 0:846135; \quad V_{guess} \ D \ 0:00085568 \ m^3 = mol$$

We compare this to the known value V^0 D 0:00101128 m^3 =mol by calculating the ratio

$$\frac{V_{guess}}{V^{0}}$$
 D 0:8461

The correct pressure must make this ratio equal to 1. Since it is less than 1 (i.e., $V_{guess} < V^0$) we must guess a lower pressure, to allow volume to increase. We choose P_{guess} D 20 bar and repeat until the ratio is sufficiently close to 1. The table below summarizes the results of these iterations.

iteration	P_{guess}	Z^0	\mathbf{Z}^1	Z_{guess}	V _{guess}	$V_{guess} = V^0$
1	24:5	0:846881	0:00762573	0:846217	0:000856171	0:84662
2	20	0:877931	0:00730925	0:877295	0:00108733	1:0752
3	22	0:864336	0:00754181	0:86368	0:000973139	0:962283
4	21	0:871173	0:00744249	0:870525	0:00102756	1:0161

The solution is somewhere between 21 and 22 bar. We continue in the same manner if we want to bracket the solution more precisely.

Problem 2.19 Solution We need to calculate densities, i.e. we need V or Z. The ideal-gas law is out of the question because the pressure is too high. Same for the truncated virial equation. We could use either the Lee-Kesler tables or an equation of state. Both methods would be appropriate since krypton is a non-polar compound.

a) We need the density of krypton, so we will first find the compressibility factor at the indicated conditions. From tables we find

The given conditions, 20 ¹C, 110 bar, correspond to reduced conditions

$$P_r D \frac{110}{55:02} D 2:0; T_r D \frac{20C 273:15}{209:4} D 1:4$$

From the Lee-Kesler tables we find (notice that we don't need Z^1 since the acentric factor is 0)

$$Z D Z^{0} D 0:7753$$

The molar volume of Kr is

The number of moles corresponding to 2000 kg of $Kr(M_w\ D\ 83:8)$ is

n D
$$\frac{2000 \text{ kg}}{83:8 \text{ 10}^{-3} \text{ kg/mol}}$$
D 23866:3 mol

and the required volume of the tank is

$$V^{tank}D \, nV \, D \, .23866:3 \, mol/.1:72 \, 10^{-4} \, m^3/\, D \, 4:1 \, m^3$$

b) We will calculate the mass in the tank when the pressure is the maximum allowable. At 180 bar, 25 1 C, we have P_{r} D 3:272; T_{r} D 1:42 1:4

From Lee-Kesler by interpolation:

$$Z D Z^{1} D 0:7202 C \frac{0:7761 0:7202}{5:0 3:0}.3:272 3:0/ D 0:7278$$

The specific volume is

$$\frac{ZRT}{P} \ D \ \frac{.0:7278 /.8:314 \ J/mol \ K/.298:15 \ K/}{180 \ 10^5 \ Pa} \ D \ 1:0 \ 10^{-4} \ m^3$$

and the number of moles of Kr in the tank is

The corresponding mass is

M D nM
$$_{W}$$
 D .40907:2 mol/.83:8 $\,$ 10 3 kg/mol/ D 3428 kg

That is, 3428 kg is the maximum mass that can be stored at $25 \, ^{1}\text{C}$ without exceeding the safety limit. It is, therefore, safe to store $2500 \, \text{kg}$.

40

Problem 2.20 We collect the following information for n-butane:

a) We need the molar volume of the liquid. Our options are: Lee-Kesler, and Rackett. We choose the Rackett equation because it is known to be fairly accurate while the accuracy of the Lee-Kesler is not very good in the liquid side. Still, if you did the problem using L-K I will consider the solution correct.

$$V\ D\ .255\ cm^3/mol/.0:274/^{.1}\ ^{293:15=425:1/}\ ^{0:2857}\ D\ 100:9\ cm^3/mol$$

The moles is

Note: This problem could also be done using the Lee-Kesler. The solution requires more calculations and the final result is very close to the above. This calculation is given at the end of this solution. b) For the volume of the vapor we use Lee-Kesler. The required interpolation is shown below.

from which we obtain the compressibility factor:

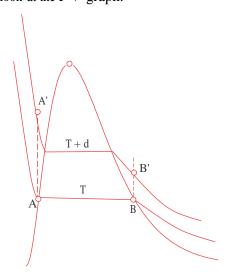

The molar volume is

$$\frac{ZR\ T}{V\ D} = \frac{0.9342/.8:314/.293:15/}{2.07 \quad 10^5} \qquad D\ 1:1 \quad 10 \quad m\ /mol$$

The moles of the vapor are

$$M_V D = \frac{10 \text{ m}^3}{1:1 - 10^{-2} \text{ m}^3/\text{mol}} D 909 \text{ mol}$$

c) To answer this question we take a look at the P V graph.

Both sides of the tank undergo constant-volume processes as indicated by the dashed lines. The graph shows the two states at the initial temperature T, as well as the states at some higher temperature, T C 1. It is obvious that the pressure in the liquid side will always be higher than the pressure of the vapor side. Therefore, the pressure of 40 bar will be reached first in the liquid side, causing that alarm to go off.

d) To calculate the temperature at the state we recall that for liquids with constant $\check{\ }$ and $\$, we have

$$\ln \frac{V_2}{V_1} D \tilde{\cdot} T \bullet P$$

SInce volume is constant, V₁ D V₂ and solving for • T we find

•T D
$$\sim$$
 D $2:54 \ 10^{-4} bar^{-1}.40 \ 2:07/bar$ D 5 1 C

The alarm will sound at T D 20 C 5 D 25 ¹C. At that point the pressure of the liquid side will be 40 bar while that of the vapor will be not much higher than 2 bar!

Calculation of liquid V using Lee-Kesler:

If you opted to do the calculation using the Lee-Kesler tables, the correct solution is shown below. First we calculate the reduced temperature and pressure.

Note: because the phase is liquid, one must extrapolate to $P_r \ D \ 0.0545$ from the listed values for the liquid (shown in the tables in italics):

With these values we obtain the following:

The answer is very close to that obtained using the Rackett equation but the Lee-Kesler method requires more calculations.

42

Problem 2.21 Solution Solution a) Filled with xenon

We need the volume of the tank which will obtain by first calculating the molar volume of xenon. We will do this calculation using the Pitzer method and the Lee Kesler tables. For xenon:

The reduced temperature and pressure are

Interpolating at $T_r \ D \ 1:4$ between Pr=1.2 and Pr=1.5 we find

Since ! D 0, Z D Z⁰ D 0:836436. Using SI units, the molar volume of xenon is

$$V\ D\ \frac{ZR\ T}{P}\ D\ .0:836436/.8:314/.405:15/82 \quad 10^5\ D\ 3:436 \quad 10^4\ m3\ /mol$$

Since the tank contains 10,000 kg, or

n D
$$\frac{10;000 \text{ kg}}{131:30 - 10^{-3} \text{ kg mol}}$$
D 76;161 mol

the volume of the tank is

Filled with steam The specific volume of steam in the tank is

$$V D \frac{26:16m^3}{10000 \text{ kg}} D 2:616 \text{ cm}^3/\text{g}$$

At 200 ¹C, the saturated volumes of water are 1.156 and 127.2 cm³/g. Since the specific volume lies between the two values, the steam is a saturated vapor/liquid mixture and the pressure is equal to the saturation pressure at 200 ¹C: P D 15:45 bar.

b) If the mass in the tank is reduced to half, the specific volume doubles:

This value is still between that of the saturated vapor and liquid, therefore the pressure remains constant.

Problem 2.22 Solution a) Vapor.

b) At 0.1 bar, 200 C, o-xylene is essentially in the ideal-gas state (why?).

$$V D \frac{RT}{P} D 0:393377 \text{ m}^3 = \text{mol}$$

The volume of the tank is

$$V^{tank}D$$
 .200 mol/.0:393377 m³=mol/ D 39:3 m³: (2.2)

c) At 44.9 bar, 200 C, the reduced temperature an pressure is

From the Lee-Kesler tables we find

The molar volume is

$$V_2 D \frac{ZR T}{P_2} D 0:000752133 m^3 = mol$$

and the number of moles

$$n \, \nu \, \frac{V^{tank}}{V_2} \, D$$
 52301:5 mol

44

Problem 2.23 Solution a) We first calculate the coefficient of thermal expansion form the empirical equation given above:

$$\stackrel{\smile}{\smile} D \stackrel{1}{\stackrel{@}{V}} \stackrel{@V}{\stackrel{@}{t}} \stackrel{@t}{\stackrel{P}{\longrightarrow}} \stackrel{@T}{\stackrel{@}{U}}$$

where t stands for temperature in celsius and T for temperature in kelvin. Using the polynomial expression given in the problem statement we find

$$D = \frac{a_1C 2a_2tC 3a_3t^2}{1 C a_1t C a_2t^2 C a_3t^3}$$

For constant pressure process,

$$\frac{dV}{V}$$
 D $\tilde{}$ dT \rightarrow $\frac{V_2}{V_1}$ D $\tilde{e}^{\tilde{}}$. T_2 $T_1/$

For this calculation we will use an average value of between 18 ¹C and 40 ¹C:

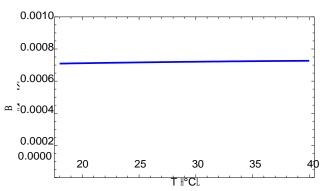

$$^{\circ}_{av}$$
 D 0:5. $^{\circ}_{18}$ C $^{\circ}_{40}$ / D 0:5.7:09 $^{-1}$ 0 $^{-4}$ C 7:27 $^{-1}$ 0 $^{-4}$ / K $^{-1}$ D 7:18 $^{-1}$ 0 $^{-4}$ K $^{-1}$

With this value, the change in volume is

$$\frac{V_2}{V_1}$$
 D 1:016

or an increase of 1/6%.

Note: We have treated `as nearly constant. To determine the validity of this assumption we make a graph of `in the temperature range of interest:

The coefficient $\check{\ }$ changes very slowly with temperature, therefore the use of an average value is justified.

b) We start with

$$\frac{dV}{V}$$
 D $\tilde{}$ dT dP :

Assuming the contained to be rigid, volume remains constant, i.e., $dV \ D \ 0$. We then integrate the above equation and solve for $\bullet P$:

$$0 \,\mathrm{D}\,\mathrm{\dot{}}\mathrm{d}\mathrm{T} \,\mathrm{d}\mathrm{P}$$
) •P D $\mathrm{\dot{}}\mathrm{\bullet}\mathrm{T}$) •P D

Numerical substitutions:

•P D
$$\frac{.7:18 - 10^{-4} \text{K}^{-1}/.22 \text{ K}/}{52 - 10^{-6} \text{ bar}}$$
 D 287 bar

Problem 2.24 Solution The numerical results are summarized in the atatched tables:

Problem 2.25 Solution

First we collect the parameters for isobutane:

$$T_c \ D \ 408:1 \ K; \quad P_c \ D \ 36:48 \ bar; \quad ! \ D \ 0:181; \quad M_w \ D \ 58:123 \quad 10^{-3} \ kg/mol$$

We are given T D 294:26 K, P D 4:13793 bar. With this information we find that the compressibility equation has three real roots:

We know that the phase is liquid (since the given temperature is below the saturation temperature at the given pressure), therefore the correct compressibility factor is the smallest of the three:

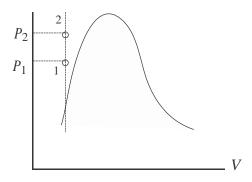

The corresponding molar volume is

The amount (moles) of isobutane is

n D
$$\frac{5000 \text{ kg}}{58:123 - 10^{-3} \text{ kg/mol}}$$
D 86024:5 mol

Therefore, the volume of the tank is

a) Before we solve the problem it is useful to look at the P V graph first.

Since the volume of the tank and the mass of isobutane remain the same, the molar volume also stays the same. In other words, the new state must be on the vertical line that passes through the initial state 1. Since temperature is higher, the final state will be above state 1 (marked as state 2 in the above figure). This is somewhat surprising: one might think that some vapor may be generated since temperature increases. Instead, the system moves firther into the compressed liquid region! This is because heating takes place under constant volume.¹

¹If heating were to take place under constant pressure insead, the final state would move to the right of state 1, possibly creating some vapor.

b) Since the total volume and mass in the tank remain the same, the molar volume must also stay the same, namely, $V D 1:09713 10^{-4} m^3/mol$

The pressure can now be calculated directly from the SRK equation:

$$\frac{RT_{V}}{V}D\frac{a}{V.VCb/}$$

Notice, however, that the parameter a must be recalculated because it depends on temperature. With T $\,$ D $\,$ 308:15 K we find

a D
$$1:68988 \, J \, m^3/mol^2$$

Using this value of a, the previous value of b, and V D 1:09713 10^{-4} m^3/mol , the SRK equation gives

This represents an increase of 66 bar even though temperature increased only by 20 ¹F! The reason is that isotherms in the compressed liquid state are very steep, resulting in large pressure change under constant-volume heating.

Problem 2.26 Solution

a) At 30 ¹C, 1 bar the SRK equation has the following three real roots. Since the phase is vapor (why?) we pick the largest root:

Z D 0:977286 V D
$$\frac{ZR T}{P}$$
 D $\frac{0:0246314m^{\frac{3}{2}}mol}{}$

b) At 30 ¹C, 10 bar the SRK equation has the following three real roots. The phase is liquid (why?), therefore we pick the smallest root:

Z D 0:0413973 V D
$$\frac{ZR T}{P}$$
 D $0:000104337m = mol$

b) At 30 ¹C, 4.05 bar the SRK equation has the following three real roots. Since the system is saturated, the smallest root is the liquid and largest is the vapor:

$$Z_L D 0:0413973; V_L D \frac{Z_L RT}{P \text{ sat}} D \underline{0:000104698m \frac{3}{2} \text{mol}}$$

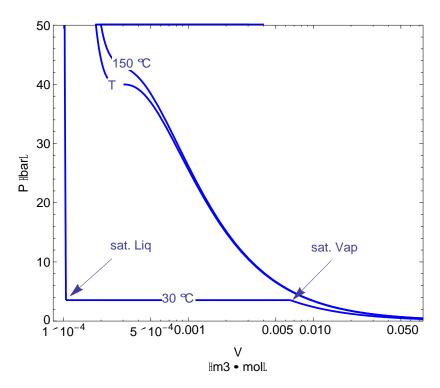

$$Z_V \ D \ 0:901582; \quad V_V \ D \ \frac{Z_V RT}{P^{\ sat}} \ D \ \underline{0:00561071m^3 = mol}$$

The literature values from the NIST Web Book are

$$V_L D 0:00010678m^3 = mol V_V D 0:0055461m^3 = mol$$

The SRK values are off by 2% (liquid) and 1:2% (vapor). These errors are pretty small.

Problem 2.27 Solution

Note: For maximum readability use semilog coordinates (linear axis for pressure, logarithmic axis for vol- ume).

Problem 2.28 Solution The the general form for the differential of V is

$$\frac{dV}{V}\;D\;\check{}\;dT \qquad dP$$

Using the given expressions for `and we have

$$d \ln V D \frac{dT}{\bullet T} \frac{dP}{P}$$

Integration is this differential from V_0 , T_0 , P_0 to V, T, P is very simple in this case because the variables happen to be separated (each of the three terms contains one variable only). The result is

$$\ln \frac{V}{V_0} \, \mathbf{D} \, \ln \frac{T}{T_0} \, \ln \frac{P}{\mathbf{P}_{\theta}}$$

The same result is obtained if we adopt an arbitrary integration path, say from T_0 , P_0 , under constant T to T_0 , P, and then under constant P to T, P. As we can easily verify, the differential of the above is indeed equal to Eq. [A]. Equation [B] can be rearranged to write

$$\ln \frac{V}{V_0} \, \mathbf{\nu} \ln \quad \frac{T}{T_0} \quad \frac{P_0}{\underline{P}} \qquad \text{or} \qquad \left[\frac{P \, V}{T} \, D \, \frac{P_0 V_0}{T_0} \right]$$

In other words we have obtained the ideal-gas law.

Based on the final result we can certainly say that this equation of state is not appropriate for liquids. Even before integration, however, we could reach the same conclusion by looking at the T and P dependence of

 $\check{}$ and . The inverse dependence of $\check{}$ on T (and of ${}$ on P) indicates that these parameters vary quite a bit with pressure and temperature. This is a characteristic of gases. The values of ${}$ and $\check{}$ for solids and liquids are typically small numbers and vary much less with temperature and pressure.

Problem 2.29 Solution Using the hint we write:

Starting with the SRK equation,

$$\begin{array}{ccc} & & RT & & a \\ P & D & \overline{V & b} & & \overline{V.V C b/} \end{array}$$

the derivative wrt V is:

Numerical substitutions

54

Problem 2.30 Solution

a) By definition,

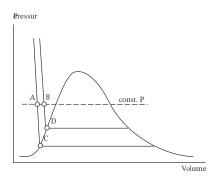

$$\sim D \frac{1}{V} \frac{@V}{@T} P$$

The partial derivative will be approximated as a finite difference between two states A and B at the same pressure:

$$\underline{@V} \qquad \underline{V_A} \quad \underline{V_B}$$

$$@T \quad {}_{\mathbf{P}} \qquad T_{A} \quad T_{B}$$

For V we must use a value between V_A and V_B . Choosing V D $V_A \subset V_B = 2$, the final result is

a) At 25¹C, 1 bar, the system is compressed liquid. Assuming the liquid to be incompressible, the required volumes are those of the saturated liquid.

The coefficient of isothermal compressibility is

- b) The answer at 10 bar is the same because the assumption of incompressibility implies that the isotherms are vertical and the molar volumes the same as in the previous part.
- c) In this case the state is superheated vapor. We select two temperatures around 200 ¹C and apply the same procedure:

$$T_{A}$$
 D 150 1 C V_{A} D 1:9367 m^{3} =kg T_{B} D 250 1 C V_{B} D 2:4062 m^{3} =kg

and we find

Problem 2.31 Solution Solution

Assuming isotherms in the compressed liquid region to be vertical, ~ is calculated as

where T_1 , T_2 are two temperatures around 24 $^{\bf 1}$ C, and V_1 , V_2 , are the volumes of the saturated liquid at these temperatures, to be calculated using the Rackett equation. With T_1 D 20 $^{\bf 1}$ C, T_2 D 30 $^{\bf 1}$ C we find

Calculation are shown in the attached notebook.
