Chapter 1 A Brief History of Risk and Return

Concept Questions

1. For both risk and return, increasing order is b, c, a, d . On average, the higher the risk of an investment, the higher is its expected return.
2. Since the price didn't change, the capital gains yield was zero. If the total return was four percent, then the dividend yield must be four percent.
3. It is impossible to lose more than -100 percent of your investment. Therefore, return distributions are cut off on the lower tail at -100 percent; if returns were truly normally distributed, you could lose much more.
4. To calculate an arithmetic return, you simply sum the returns and divide by the number of returns. As such, arithmetic returns do not account for the effects of compounding. Geometric returns do account for the effects of compounding and for changes in the base used for each year's calculation of returns. As an investor, the more important return of an asset is the geometric return.
5. Blume's formula uses the arithmetic and geometric returns along with the number of observations to approximate a holding period return. When predicting a holding period return, the arithmetic return will tend to be too high and the geometric return will tend to be too low. Blume's formula adjusts these returns for different holding period expected returns.
6. T-bill rates were highest in the early eighties since inflation at the time was relatively high. As we discuss in our chapter on interest rates, rates on T-bills will almost always be slightly higher than the expected rate of inflation.
7. Risk premiums are about the same whether or not we account for inflation. The reason is that risk premiums are the difference between two returns, so inflation essentially nets out.

8. Returns, risk premiums, and volatility would all be lower than we estimated because aftertax returns are smaller than pretax returns.

9. We have seen that T-bills barely kept up with inflation before taxes. After taxes, investors in T-bills actually lost ground (assuming anything other than a very low tax rate). Thus, an all T-bill strategy will probably lose money in real dollars for a taxable investor.
10. It is important not to lose sight of the fact that the results we have discussed cover over 80 years, well beyond the investing lifetime for most of us. There have been extended periods during which small stocks have done terribly. Thus, one reason most investors will choose not to pursue a 100 percent stock (particularly small-cap stocks) strategy is that many investors have relatively short horizons, and high volatility investments may be very inappropriate in such cases. There are other reasons, but we will defer discussion of these to later chapters.

Solutions to Questions and Problems

NOTE: All end of chapter problems were solved using a spreadsheet. Many problems require multiple steps. Due to space and readability constraints, when these intermediate steps are included in this solutions manual, rounding may appear to have occurred. However, the final answer for each problem is found without rounding during any step in the problem.

Core Questions

- Total dollar return = $100(\$41 - 37 + 0.28) = \428.00
Whether you choose to sell the stock or not does not affect the gain or loss for the year; your stock is worth what it would bring if you sold it. Whether you choose to do so or not is irrelevant (ignoring commissions and taxes).
- Capital gains yield = $(\$41 - 37) / \$37 = 10.81\%$
Dividend yield = $\$0.28 / \$37 = 0.76\%$
Total rate of return = $10.81\% + 0.76\% = 11.57\%$
- Dollar return = $500(\$34 - 37 + 0.28) = -\$1,360$
Capital gains yield = $(\$34 - 37) / \$37 = -8.11\%$
Dividend yield = $\$0.28 / \$37 = 0.76\%$
Total rate of return = $-8.11\% + 0.76\% = -7.35\%$
- average return = 6.2%, average risk premium = 2.5%
 - average return = 3.7%, average risk premium = 0%
 - average return = 11.7%, average risk premium = 8.0%
 - average return = 17.5%, average risk premium = 13.8%
- Cherry average return = $(17\% + 11\% - 2\% + 3\% + 14\%) / 5 = 8.60\%$
Straw average return = $(16\% + 18\% - 6\% + 1\% + 22\%) / 5 = 10.20\%$
- Cherry: $R_A = 8.60\%$
Var = $1/4[(.17 - .086)^2 + (.11 - .086)^2 + (-.02 - .086)^2 + (.03 - .086)^2 + (.14 - .086)^2] = .00623$
Standard deviation = $(0.00623)^{1/2} = .0789$, or 7.89%

Straw: $R_B = 10.20\%$
Var = $1/4[(.16 - .102)^2 + (.18 - .102)^2 + (-.06 - .102)^2 + (.01 - .102)^2 + (.22 - .102)^2] = .01452$
Standard deviation = $(0.01452)^{1/2} = .1205$, or 12.05%
- The capital gains yield is $(\$59 - 65)/\$65 = -.0923$, or -9.23% (notice the negative sign). With a dividend yield of 1.2 percent, the total return is -8.03%.
- Geometric return = $[(1 + .17)(1 + .11)(1 - .02)(1 + .03)(1 + .14)]^{(1/5)} - 1 = .0837$, or 8.37%
- Arithmetic return = $(.21 + .12 + .07 - .13 - .04 + .26) / 6 = .0817$, or 8.17%
Geometric return = $[(1 + .21)(1 + .12)(1 + .07)(1 - .13)(1 - .04)(1 + .26)]^{(1/6)} - 1 = .0730$, or 7.30%

Intermediate Questions

10. That's plus or minus one standard deviation, so about two-thirds of the time, or two years out of three. In one year out of three, you will be outside this range, implying that you will be below it one year out of six and above it one year out of six.
11. You lose money if you have a negative return. With a 12 percent expected return and a 6 percent standard deviation, a zero return is two standard deviations below the average. The odds of being outside (above or below) two standard deviations are 5 percent; the odds of being below are half that, or 2.5 percent. (It's actually 2.28 percent.) You should expect to lose money only 2.5 years out of every 100. It's a pretty safe investment.
12. The average return is 6.2 percent, with a standard deviation of 12.2 percent, so $\text{Prob}(\text{Return} < -6.0 \text{ or } \text{Return} > 18.4) \approx 1/3$, but we are only interested in one tail; $\text{Prob}(\text{Return} < -6.0) \approx 1/6$, which is half of $1/3$.
 95%: $6.2 \pm 2\sigma = 6.2 \pm 2(12.2) = -18.2\% \text{ to } 30.6\%$
 99%: $6.2 \pm 3\sigma = 6.2 \pm 3(12.2) = -30.4\% \text{ to } 42.8\%$
13. Expected return = 17.5% ; $\sigma = 36.6\%$. Doubling your money is a 100% return, so if the return distribution is normal, $Z = (100 - 17.5)/36.6 = 2.25$ standard deviations; this is in-between two and three standard deviations, so the probability is small, somewhere between .5% and 2.5% (why?). Referring to the nearest Z table, the actual probability is = 1.209%, or about once every 100 years. Tripling your money would be $Z = (200 - 17.5)/36.6 = 4.986$ standard deviations; this corresponds to a probability of (much) less than 0.5%, or once every 200 years. (The actual answer is less than once every 1 million years, so don't hold your breath.)

14.	<u>Year</u>	<u>Common stocks</u>	<u>T-bill return</u>	<u>Risk premium</u>
	1973	-14.69%	7.29%	-21.98%
	1974	-26.47%	7.99%	-34.46%
	1975	37.23%	5.87%	31.36%
	1796	23.93%	5.07%	18.86%
	1977	-7.16%	5.45%	-12.61%
	sum	12.84%	31.67%	-18.83%

- a. Annual risk premium = Common stock return – T-bill return (see table above).
- b. Average returns: Common stocks = $12.84 / 5 = 2.57\%$; T-bills = $31.67 / 5 = 6.33\%$;
 Risk premium = $-18.83 / 5 = -3.77\%$
- c. Common stocks: $\text{Var} = 1/4[(-.1469 - .0257)^2 + (-.2647 - .0257)^2 + (.3723 - .0257)^2 + (.2393 - .0257)^2 + (-.0716 - .0257)^2] = .072337$
 Standard deviation = $(.072337)^{1/2} = .2690 = 26.90\%$
 T-bills: $\text{Var} = 1/4[(.0729 - .0633)^2 + (.0799 - .0633)^2 + (.0587 - .0633)^2 + (.0507 - .0633)^2 + (.0545 - .0633)^2] = .0001565$
 Standard deviation = $(.0001565)^{1/2} = .0125 = 1.25\%$
 Risk premium: $\text{Var} = 1/4[(-.2198 - (-.0377))^2 + (-.3446 - (-.0377))^2 + (.3136 - (-.0377))^2 + (.1886 - (-.0377))^2 + (-.1261 - (-.0377))^2] = .077446$
 Standard deviation = $(.077446)^{1/2} = .2783 = 27.83\%$

d. Before the fact, the risk premium will be positive; investors demand compensation over and above the risk-free return to invest their money in the risky asset. After the fact, the observed risk premium can be negative if the asset's nominal return is unexpectedly low, the risk-free return is unexpectedly high, or any combination of these two events.

15. $(\$324,000 / \$1,000)^{1/50} - 1 = .1226$, or 12.26%

16. 5 year estimate = $[(5 - 1)/(40 - 1)] \times 10.24\% + [(40 - 5)/(40 - 1)] \times 12.60\% = 12.36\%$
 10 year estimate = $[(10 - 1)/(40 - 1)] \times 10.24\% + [(40 - 10)/(40 - 1)] \times 12.60\% = 12.06\%$
 20 year estimate = $[(20 - 1)/(40 - 1)] \times 10.24\% + [(40 - 20)/(40 - 1)] \times 12.60\% = 11.45\%$

17. Small company stocks = $(\$21,997.36 / \$1)^{1/87} - 1 = .1218$, or 12.18%
 Large company stocks = $(\$3,247.50 / \$1)^{1/87} - 1 = .0974$, or 9.74%
 Long-term government bonds = $(\$112.14 / \$1)^{1/87} - 1 = .0557$, or 5.57%
 Treasury bills = $(\$22.39 / \$1)^{1/87} - 1 = .0364$, or 3.64%
 Inflation = $(\$12.83 / \$1)^{1/87} - 1 = .0298$, or 2.98%

18. $R_A = (-.09 + .17 + .09 + .14 - .04) / 5 = .0540$, or 5.40%
 $R_G = [(1 - .09)(1 + .17)(1 + .09)(1 + .14)(1 - .04)]^{1/5} - 1 = .0490$, or 4.90%

19. $R_1 = (\$15.61 - 13.25 + 0.15) / \$13.25 = 18.94\%$
 $R_2 = (\$16.72 - 15.61 + 0.18) / \$15.61 = 8.26\%$
 $R_3 = (\$15.18 - 16.72 + 0.20) / \$16.72 = -8.01\%$
 $R_4 = (\$17.12 - 15.18 + 0.24) / \$15.18 = 14.36\%$
 $R_5 = (\$20.43 - 17.12 + 0.28) / \$17.12 = 20.97\%$
 $R_A = (.1894 + .0826 - .0801 + .1436 + .2097) / 5 = .1090$, or 10.90%
 $R_G = [(1 + .1894)(1 + .0826)(1 - .0801)(1 + .1436)(1 + .2097)]^{1/5} - 1 = .1038$, or 10.38%

20. Stock A: $R_A = (.08 + .08 + .08 + .08 + .08) / 5 = .0800$, or 8.00%
 $\text{Var} = 1/4[(.08 - .08)^2 + (.08 - .08)^2 + (.08 - .08)^2 + (.08 - .08)^2 + (.08 - .08)^2] = .000000$
 Standard deviation = $(.000)^{1/2} = .000$, or 0.00%
 $R_G = [(1 + .08)(1 + .08)(1 + .08)(1 + .08)(1 + .08)]^{1/5} - 1 = .0800$, or 8.00%

Stock B: $R_A = (.03 + .13 + .07 + .05 + .12) / 5 = .0800$, or 8.00%
 $\text{Var} = 1/4[(.03 - .08)^2 + (.13 - .08)^2 + (.07 - .08)^2 + (.05 - .08)^2 + (.12 - .08)^2] = .001900$
 Standard deviation = $(.001900)^{1/2} = .0436$, or 4.36%
 $R_G = [(1 + .03)(1 + .13)(1 + .07)(1 + .05)(1 + .12)]^{1/5} - 1 = .0793$, or 7.93%

Stock C: $R_A = (-.24 + .37 + .14 + .09 + .04) / 5 = .0800$, or 8.00%
 $\text{Var} = 1/4[(-.24 - .08)^2 + (.37 - .08)^2 + (.14 - .08)^2 + (.09 - .08)^2 + (.04 - .08)^2] = .047950$
 Standard deviation = $(.047950)^{1/2} = .2190$, or 21.90%
 $R_G = [(1 - .24)(1 + .37)(1 + .14)(1 + .09)(1 + .04)]^{1/5} - 1 = .0612$, or 6.12%

The larger the standard deviation, the greater will be the difference between the arithmetic return and geometric return. In fact, for lognormally distributed returns, another formula to find the geometric return is: arithmetic return - 1/2 variance. Therefore, for Stock C, we get $.0800 - 1/2(.047950) = .0560$. The difference in this case is because the return sample is not a true lognormal distribution.

35								
36			Because the investor deposited more money (i.e., had the most invested) prior/during the worst return years, the dollar weighted return is lower.					
37								

CFA Exam Review by Schweser

1. a

$$\text{Geometric average return} = [(.9)(1.25)(.95)(1.30)(1.05)]^{1/5} - 1 = 7.85\%$$

2. b

	Scenario 2	Scenario 3
CF ₀	-100	-100
CF ₁	0	0
CF ₂	-20	+10
CF ₃	0	0
CF ₄	0	0
CF ₅	171.82	132.92
IRR	7.96%	7.78%

Scenario 2 Ending MV

$$\text{End of Year 2} = 100(.9)(1.25) + 20 = 132.5$$

$$\text{End of Year 5} = 132.5(.95)(1.30)(1.05) = 171.8194$$

Scenario 3 Ending MV

$$\text{End of Year 2} = 100(.9)(1.25) - 10 = 102.5$$

$$\text{End of Year 5} = 102.5(.95)(1.30)(1.05) = 132.9169$$

3. c

$$\text{Annualized return} = (1.0163)^{12} - 1 = 21.412\%$$

4. b

Geometric returns provide the best estimate of a portfolio manager's return because it neutralizes the impact of the client's cash flow decisions. For the clients themselves, the dollar weighted return would be appropriate.
